ABSTRACT

This paper deals with the use of the vector levelings for coding color images, a class of morphological connected filters which suppresses details but preserves the contours of the remaining objects. If the color images are filtered by independently leveling each color component, new colors may be introduced. In order to avoid this drawback, a total order must be imposed on the color vectors. A comparative study has been drawn for various lexicographical orders in the RGB and the HLS color systems. These filters can be especially useful as a preprocessing step for improving the compression of color images.

1. INTRODUCTION

The morphological connected filters have the nice property to suppress details but preserve the contours of the remaining objects. Levelings are a subclass of symmetric connected operators that have originally been defined and studied for grey tone images [7]. Several extensions to vector spaces have been proposed: pseudo-scalar and autarkical levelings [2], separable levelings [8] and non-separable levelings [12]. In this paper, we deal with the implementation of vector levelings in complete totally ordered lattices by using lexicographical orders which are defined on the RGB color space and on an improved HLS system (recently proposed [5]). After a comparative study of the performance of different orders, these color filters are applied to the morphological coding of color images.

2. MATHEMATICAL MORPHOLOGY IN COLOR COMPLETE TOTALLY ORDERED LATTICES

Mathematical morphology is a non-linear image processing approach which is based on the application of lattice theory to spatial structures [10]. In practice, the definition of morphological operators needs a totally ordered complete lattice structure ($x \leq y$ or $y \leq x$ for every pair x and y ; and every finite subset has a supremum and an infimum) [11]: there are no pair of points for which the order is uncertain. The

application of mathematical morphology to color images is difficult due to the vectorial nature of the color data. Many research works have been carried out on the application of mathematical morphology to color images [6, 3, 4, 9]. The most commonly adopted approach is based on the use of a lexicographical order which imposes a total order on the vectors. Let $\mathbf{x} = (x_1, x_2, \dots, x_n)$ and $\mathbf{y} = (y_1, y_2, \dots, y_n)$ be two arbitrary vectors ($\mathbf{x}, \mathbf{y} \in Z^n$), an example of *lexicographical order* may be

$$\mathbf{x} < \mathbf{y} \text{ if } \begin{cases} x_1 < y_1 & \text{or} \\ x_1 = y_1 & \text{and} \quad x_2 < y_2 \quad \text{or} \dots \\ x_1 = y_1 & \text{and} \quad x_2 = y_2 \dots \quad x_n < y_n \end{cases}$$

In this case the priority is given to the first component, then to the second, etc. Obviously, it is possible to define other orders for imposing a dominant role to any other of the vector components. As previous works have shown [9], the drawback of these kinds of orders is that most of vector pairs are sorted by the chosen first component. There is a simple way in order to make the lexicographical order more flexible (reducing the excessive dependence of the first component) which involves the linear reduction of the dynamic margin of the first component, applying a division by a constant and rounding off. Therefore, we can propose an α -modulus lexicographical order

$$\mathbf{x} <_{\alpha} \mathbf{y} \begin{cases} \lceil x_1/\alpha \rceil < \lceil y_1/\alpha \rceil & \text{or} \\ \lceil x_1/\alpha \rceil = \lceil y_1/\alpha \rceil & \text{and} \quad x_2 < y_2 \quad \text{or} \dots \\ \lceil x_1/\alpha \rceil = \lceil y_1/\alpha \rceil & \text{and} \quad x_2 = y_2 \dots \quad x_n < y_n \end{cases}$$

The choice of the value for α controls the degree of influence of the first component with regard to the others (above all the second one). These orders can be applied to the color spaces. Let $\mathbf{f}(p) = (f_R(p), f_G(p), f_B(p))$ and $\mathbf{f}(p) = (f_H(p), f_L(p), f_S(p))$ be the color values of the pixel p from the color image \mathbf{f} in the RGB and HLS color spaces respectively.

The use of a lexicographical order directly in the RGB space requires that one of the color must be arbitrarily elevated to a dominant role. To avoid this, a first approach entails calculating the max and the

min of the three RGB values for every pixel; i.e. $M(\mathbf{f})(p) = \max(f_R(p), f_G(p), f_B(p))$ and $m(\mathbf{f})(p) = \min(f_R(p), f_G(p), f_B(p))$. Then for every pair of pixels p and q we can build a lexicographical order where the first component is given by M , the second one is associated to m and, if $M(p) = M(q)$ and $m(p) = m(q)$ then the choice of the RGB components does not have a significant influence; e.g. the green component can be taken into account then the red and finally the blue (M, m, f_G, f_R, f_B). We named this order $Mm - RGB$. Preliminary tests showed that the application of morphological operators based on the $Mm - RGB$ lattice yields strange visual effects. In order to improve the visual effects, we propose an α -modulus lexicographical order where the first component is given by a function of ordering I ,

$$I(p) = \beta[\kappa_1 f_R(p) + \kappa_2 f_G(p) + \kappa_3 f_B(p)] + (1 - \beta)[\max(f_R(p), f_G(p), f_B(p)) - \min(f_R(p), f_G(p), f_B(p))], \quad 0 \leq \beta \leq 1.$$

In the function I there are a linear combination of RGB components (i.e., a luminance value) and the max – min of the components (i.e., a saturation value), weighted by β . After deep tests, we have found that the values $\kappa_1 = 0.3, \kappa_2 = 0.6, \kappa_3 = 0.1$ and $\beta = 0.8$ yield very good visual effects. Due to the fact that the luminance gives much importance to the green component, the other components for ordering can be: the red, then the green and finally, the blue (I, f_R, f_G, f_B). A similar approach has been used for the interpolation of color images [6]. The order is called $I - RGB_\alpha$ and in Figure 1 are shown two examples of color leveling with this order.

The more homogenous HLS 3D-polar coordinate color representation may be used to define other interesting lexicographical orders. For this space, we adopted the lattices introduced in [3]. The hue is an angular component, therefore in order to be able to define a total order we must choose a hue origin H_0 (typically associated to the dominant color), i.e. using only the hue, $p < q$ if $f_H(p) + H_0 > f_H(q) + H_0$. Having this constraint, we can define two α -modulus lexicographical orders: luminance-based LSH_{α, H_0} (luminance, saturation and centred hue) and saturation-based SLH_{α, H_0} (saturation, luminance and centred hue). We have implemented also a lexicographical order with the hue component in the first level however, as pointed out in [3], the hue-based order is very unstable. The authors proposed a solution which is based on a weighting of the hue by the saturation, i.e. $f'_H(p) = f_H(p) - H_0$ if $f_H(p) - H_0 \geq 0^\circ$ or $f'_H(p) = 360^\circ + f_H(p) - H_0$ if $f_H(p) - H_0 < 0^\circ$ and the following weighting, $f''_H(p) = \sup(f'_H(p), 90(1 - f_S(p))), 0 \leq f'_H(p) < 90$ or $f''_H(p) = \inf(f'_H(p), 90(1 + f_S(p))), 90 \leq f'_H(p) < 180$ or $f''_H(p) = \sup(f'_H(p), 90(3 - f_S(p))), 180 \leq f'_H(p) < 270$ or $f''_H(p) = \inf(f'_H(p), 90(3 + f_S(p))), 270 \leq f'_H(p) <$

360. Now it is possible to define the hue-based order H^*SL , with the hue weighted value $f''_H(p)$ as first component ($p < q$ if $f''_H(p) > f''_H(q)$, then the saturation and then the luminance). The application of LSH_{α, H_0} yields the best visual effects and consequently it is the most indicated for coding. The use of the saturation as priority for ordering can be interesting for feature extraction, segmentation, etc. [5] but the visual effects are annoying. The use of the H^*SL results in inconvenient visual artefacts, mainly due to the fact that the influence of the choice for a dominant color is very important. This last lattice may be interesting for emphasising a particular color or for removing color regions but hardly for coding.

Fig. 1. Example of color levelings using the lexicographic order $I - RGB_{\alpha=10}$ on Lenna image: (a) Reference image, f . (b) Marker (ASF of size 5), m_1 . (c) Leveled image, $\Lambda(f, m_1)$. (d) Marker (ASF of size 15), m_2 . (e) Leveled image, $\Lambda(f, m_2)$.

3. ALGORITHMIC FRAMEWORK

Once these orders have been defined, the morphological operators are defined in the standard way. The vector *erosion* of a color image \mathbf{f} at pixel x by the structuring element B

of size n is

$$\varepsilon_{nB}(\mathbf{f})(x) = \{\mathbf{f}(y) : \mathbf{f}(y) = \inf[\mathbf{f}(z)], z \in n(B_x)\},$$

and the corresponding *dilation* δ_{nB} is obtained by replacing the inf by a sup. An *opening* γ_{nB} is an erosion followed by a dilation, and a *closing* φ_{nB} is a dilation followed by an erosion. A leveling takes as arguments two images, a reference function \mathbf{f} and a marker function \mathbf{m} (generally, the marker is a roughly simplified version of the reference image). The implementation of the *leveling* $\Lambda(\mathbf{f}, \mathbf{m})$ has been programmed by means of an iterative algorithm with geodesic dilations and geodesic erosions until idempotence [7, 2], i.e. $\Lambda(\mathbf{f}, \mathbf{m})^i = \sup\{\inf[\mathbf{f}, \delta^i(\mathbf{m})], \varepsilon^i(\mathbf{m})\}$, until $\Lambda(\mathbf{f}, \mathbf{m})^i = \Lambda(\mathbf{f}, \mathbf{m})^{i+1}$. In order to have auto-dual levelings the marker function must be auto-dual. We have used two families of auto-dual markers: the *alternate sequential filters* (ASF), $ASF(\mathbf{f})_{nB} = \varphi_{nB}\gamma_{nB} \cdots \varphi_{2B}\gamma_{2B}\varphi_B\gamma_B(\mathbf{f})$ and the *vector median filters* (VMF), where the output corresponds to the color vector that minimises the sum of distances in the neighbourhood nB [1]. The purpose of this study has been the comparison of the filters obtained for the five orders above presented, therefore we have programmed a generic “vector preserving” function for every morphological color operator (using optimal algorithms for the basic erosion/dilation). In the corresponding operator, an input variable allows to define the max and min of two color pixels according to the lexicographical order used. In conclusion, for each considered ordering we need only to build two additional max / min functions.

4. EXPERIMENTAL RESULTS

Apart from the visual effects (a subjective evaluation) of the different lexicographical orders discussed above, an objective evaluation of the obtained levelings has been carried out. Five color images have selected and for every image, six levelings have been computed using as markers: three ASF’s of size $n = 5, 10$ and 15 (B is an square) and three VMF of size $7 \times 7, 11 \times 11$ and 11×11 applied two times. Moreover, this series of filters has been obtained for an example of each of the presented five lexicographical orders (notice that the VMF markers, obtained from the RGB components, are always the same). For the α -modulus lexicographical orders, the value of $\alpha = 10$ has shown to achieve robust and nice levelings. The origin of the hue has been imposed to $H_0 = 0^\circ$. Then for every pair of initial image / leveled image, two parameters of quality have been calculated: the *Signal-to-Noise Ratio* SNR and the *Percentage of Reduction in the Number of Flat Zones* FZR (connected components of the image with constant color value). In Tables 1 and 2 are included the average values on the six images for SNR and FZR . As we

ASF, $n = 5$	Ω_1	Ω_2	Ω_3	Ω_4	Ω_5
<i>SNR</i> (dB)	21,9	22,1	22,4	17,4	17,8
<i>FZR</i> (%)	37,1	37,5	38,0	40,0	39,4
ASF, $n = 10$	Ω_1	Ω_2	Ω_3	Ω_4	Ω_5
<i>SNR</i> (dB)	18,3	18,7	19,1	15,5	14,3
<i>FZR</i> (%)	44,3	44,8	45,3	46,4	46,4
ASF, $n = 15$	Ω_1	Ω_2	Ω_3	Ω_4	Ω_5
<i>SNR</i> (dB)	16,6	16,7	17,2	13,9	14,3
<i>FZR</i> (%)	48,9	49,8	50,1	51,7	49,6

Table 1. Average values of SNR and FZR using *ASF* as markers for the levelings and where $\Omega_1 = Mm - RGB$, $\Omega_2 = I - RGB_{\alpha=10}$, $\Omega_3 = LSH_{\alpha=10; H_0=0^\circ}$, $\Omega_4 = SLH_{\alpha=10; H_0=0^\circ}$ and $\Omega_5 = H^*SL_{H_0=0^\circ}$.

VMF,7×7	Ω_1	Ω_2	Ω_3	Ω_4	Ω_5
<i>SNR</i> (dB)	23,8	24,1	24,0	22,3	22,2
<i>FZR</i> (%)	33,6	34,1	31,0	26,9	31,1
VMF,11×11	Ω_1	Ω_2	Ω_3	Ω_4	Ω_5
<i>SNR</i> (dB)	21,9	22,7	22,3	20,0	20,6
<i>FZR</i> (%)	39,9	40,3	37,6	34,2	33,5
VMF,$11 \times 11(\times 2)$	Ω_1	Ω_2	Ω_3	Ω_4	Ω_5
<i>SNR</i> (dB)	20,8	21,4	20,9	18,9	19,4
<i>FZR</i> (%)	44,9	45,3	43,2	38,5	37,8

Table 2. Idem. using *VMF* as markers for the levelings.

can observe, using the *ASF*’s the best FZR corresponds to the lattices SLH and H^*SL which are however the worst lattices with respect to SNR . A good balance is given by the lattices $I - RGB$ and LSH , with results a little bit better for LSH . In the case of *VMF*’s, owing to the fact that the medians are computed in the RGB space, the values of SNR and FZR are a little better for $I - RGB$ although the values for LSH are clearly upper than for SLH or H^*SL .

5. APPLICATION: IMPROVED COMPRESSION

The most widespread image compression algorithms as JPEG (or MPEG for video sequences) are based on a transform coding scheme. It partitions an image into blocks, computes the discrete cosine transform (DCT) of each block and codes each DCT component according to a quantization scheme as a function of the magnitude of the component. The compression is greatest for constant or slowly varying blocks since these can be described by just a few DCT components. The best color levelings may be useful for the pre-processing of images for JPEG compression. The idea is to simplify the original image as much as possible without losing meaningful content. Obviously, the size of the removed structures is given by the size of the marker function used. Figure 2 depicts an example of this approach using a

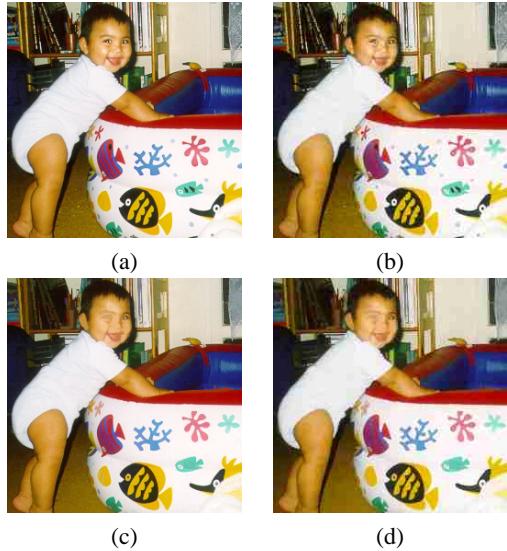

Fig. 2. Application to compression by JPEG on *Carmen* image: (a) Initial image (raster file 196662 bytes), (b) compressed initial image with quality 20% (6477 bytes), (c) leveled image, (d) compressed leveled image with quality 20% (5742 bytes).

leveling on $LSH_{\alpha=10}$ with a $VMF_{11 \times 11}$. In the leveled image, small details have been removed (see the black pupils of baby *Carmen* and the letters on the books) but, in the compressed initial image these details become diffused and therefore their suppression may be useful in order to have a clear image. The most interesting is the size reduction of 13% when applying the compression on the leveled image. For an image more abundant in details, the size reduction can be really significant; for instance the same leveling and the same compression quality applied to the standard *Baboon* image yield a reduction of 30% and for the leveling of *Lenna* image from Figure 1(e) the reduction is upper than 35%.

6. CONCLUSION

We discussed the use of lexicographical orders in the RGB and HLS color spaces for the implementation of vector levelings. It can be concluded that the most interesting lattice for morphological simplification and coding of color images is $LSH_{\alpha=10}$ (luminance, saturation, centred hue) since besides nice visual effects, it yields a good performance with regard to the *SNR* and the enlargement of flat zones. We showed the performance of vectorial levelings for improving the JPEG compression of color images.
