# PLAN

- **Introduction**
  - sequences
- **Watershed Based Segmentation :**
  - still images
  - motion (image sequences)
  - Discussion
- **"Bottom-up" Approach by Regions Merging:**
  - still images
  - image sequences
- **Results**

# IMAGE SEQUENCES

- **What is a sequence?**
  - a time succession of 2D images.
- **Main feature of a sequence :**
  - a strong time redundancy
- **How to use it ?**
  - by designing time robust segmentations.

# PURPOSES FOR SEQUENCE ANALYSIS

- **Movies and Video:**
  - restoration of old movies ;
  - image compression and/or coding ;
- **Robotics :**
  - automatic control and tracking of persons or objects ;
  - automatic car driving ;
- **Physico-Chemistry :**
  - quality control by vision may concern sequences : chemical reactions, deformations under constraints, etc...
- **Challenge : try and extract significant features from the variation along the time.**

# PROCESSINGS UNDER TIME DIMENSION

Is it preferable :

- to process each plane independently,
- or to consider the product Space  $\otimes$  time as a whole,
- or to condition the processing of plane  $t$  by the content of plane  $t-1$  ?

*2D  
approach*

*3D approach*

*Recursive approach*

## 2D APPROACH

Independent segmentations of the successive images

*Image n° i*

*Image n° i + 1*

# 3D APPROACH

**Principle :** The stack of images is considered as a **unique** image of three dimensions. However, the processing may be preferential in time direction

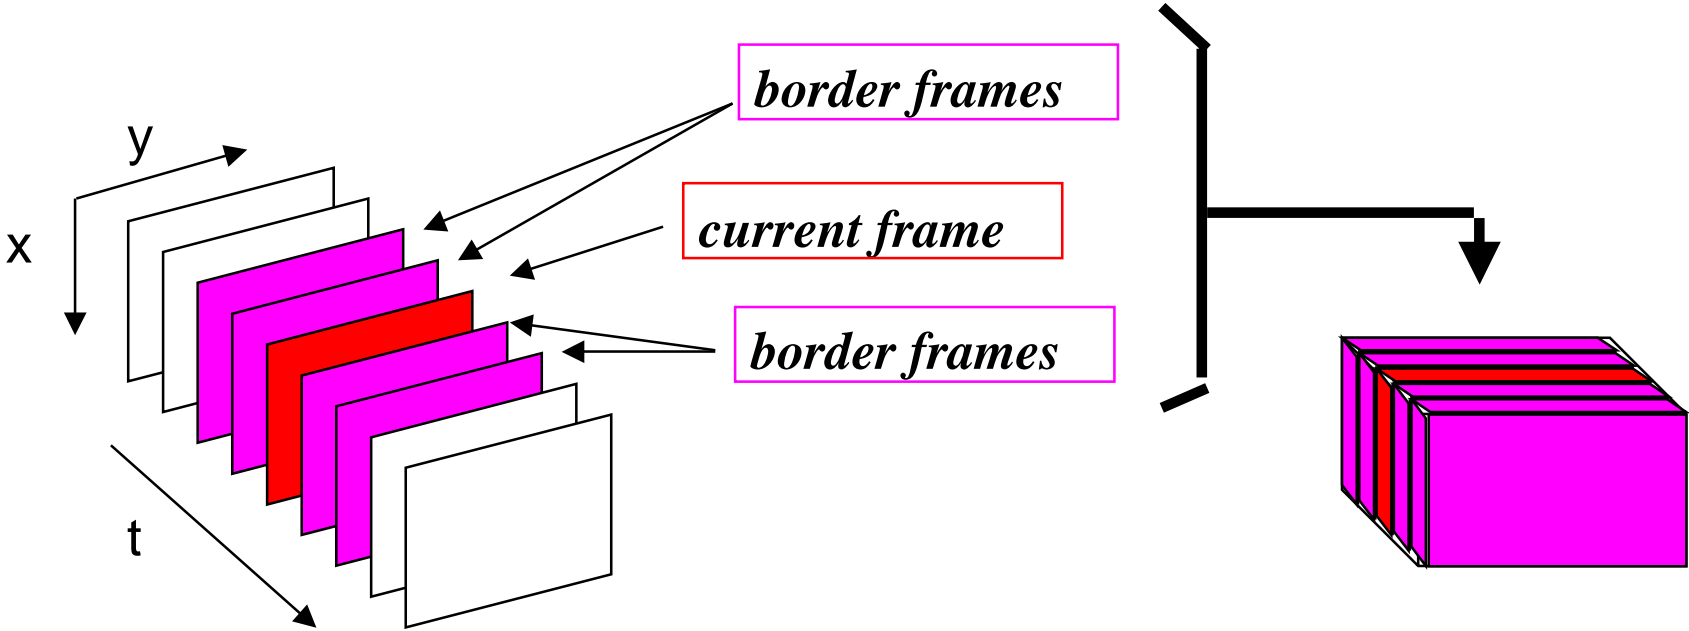

Image Sequence

Working Image

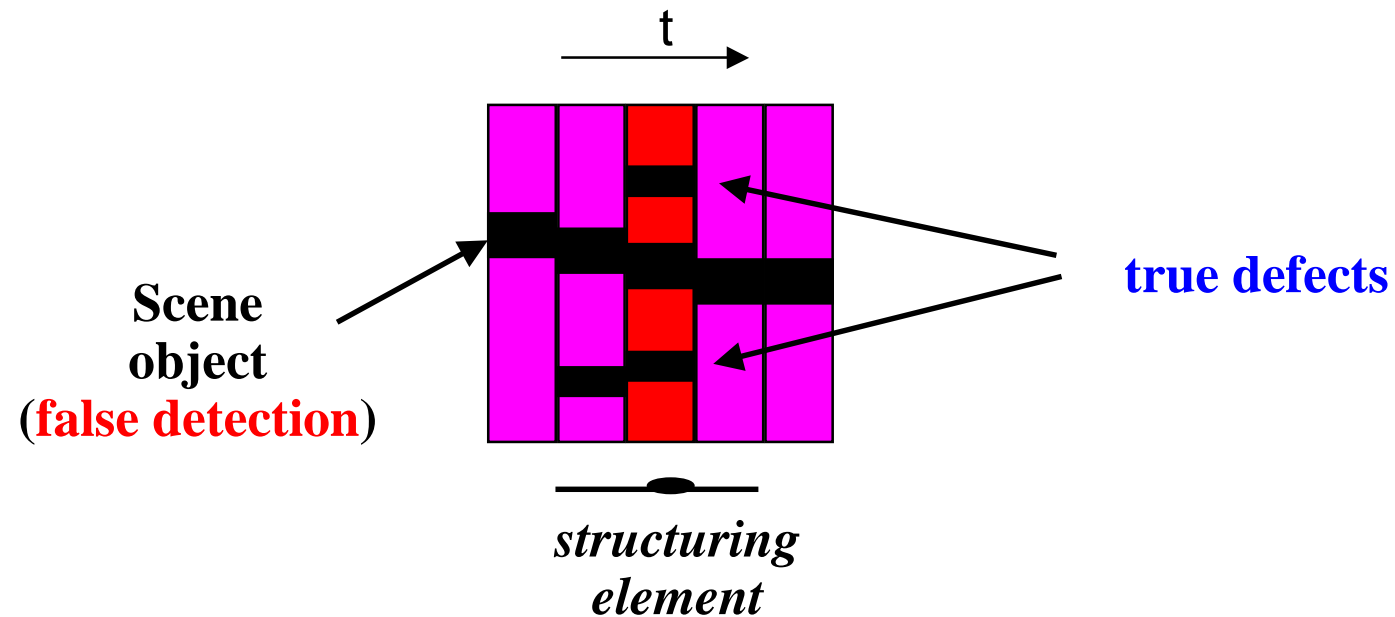

# 3D APPROACH : RESTORATION OF OLD MOVIES

Detection along the time axis

sorting between  
**false detections**  
and **true defects**

**METHOD:** top-hat by reconstruction along the time axis

## EXAMPLE OF 3D CONNECTED FILTERING

Louis Lumière's movie intitled "Arrival at Sydney Station", 1898 .

*Initial image,  
extracted from the sequence*

*filtered image*

## REMINDER : MORPHOLOGICAL SEGMENTATION

The classical morphological segmentation paradigm comprises the three following steps :

- **1 Simplification**: removes non pertinent features of the image

**CONNECTED FILTERS**

- **2 Marking** : places a marker inside every homogeneous region

**DYNAMICS**

- **3 Markers growth** : draws the contours of the marked objects

**WATERSHEDS**

## REMINDER : CONNECTED FILTERING

The connected filter chosen here is a closing $\circ$ opening by flat zones areas

- *Original image*
- *16717 regions*

- *Area filter, size 60*
- *9424 regions*

# REMINDER : MARKERS EXTRACTION

- *The 75 markers of higher dynamics*

- *Number of regions versus the dynamics of the gradient*

# REMINDER : VARIOUS CHOICES OF MARKERS

*Markers  
extraction by  
dynamics*

*Markers extraction  
by dynamics and  
sizes*

## AN EXAMPLE : ROAD DETECTION

**Method** : The inside marker is the erosion of segmentation  $n^{\circ} t-1$ , and the outside one is the upper horizontal line of the field (the sky).

*Initial image  $n^{\circ} t$*

*Segmentation of image  $n^{\circ} t$*

# A COUNTER EXAMPLE

*gradient =  
dilation-erosion*

uncertain  
contours  
locations

## CONCLUSIONS

The usual 2-D morphological segmentation, which is based on the marked watershed of the gradient,

- cannot manage the **arrival of new regions** (note that in some simple cases, the number of regions remains constant: *e.g.* road segmentation);
- in addition, the 3D **gradients are coarser** than the 2D ones, which makes the limits of the regions not precise.

# WHAT TO DO ?

To keep using a model  
which needs band aid ?

...or to look for  
a new paradigm ?

## REGION MERGING (I)

- **Definition :**

- $P_i$  is a partition of the image. The most similar adjacent regions of  $P_i$  merge, which generates partition  $P_{i+1}$ .

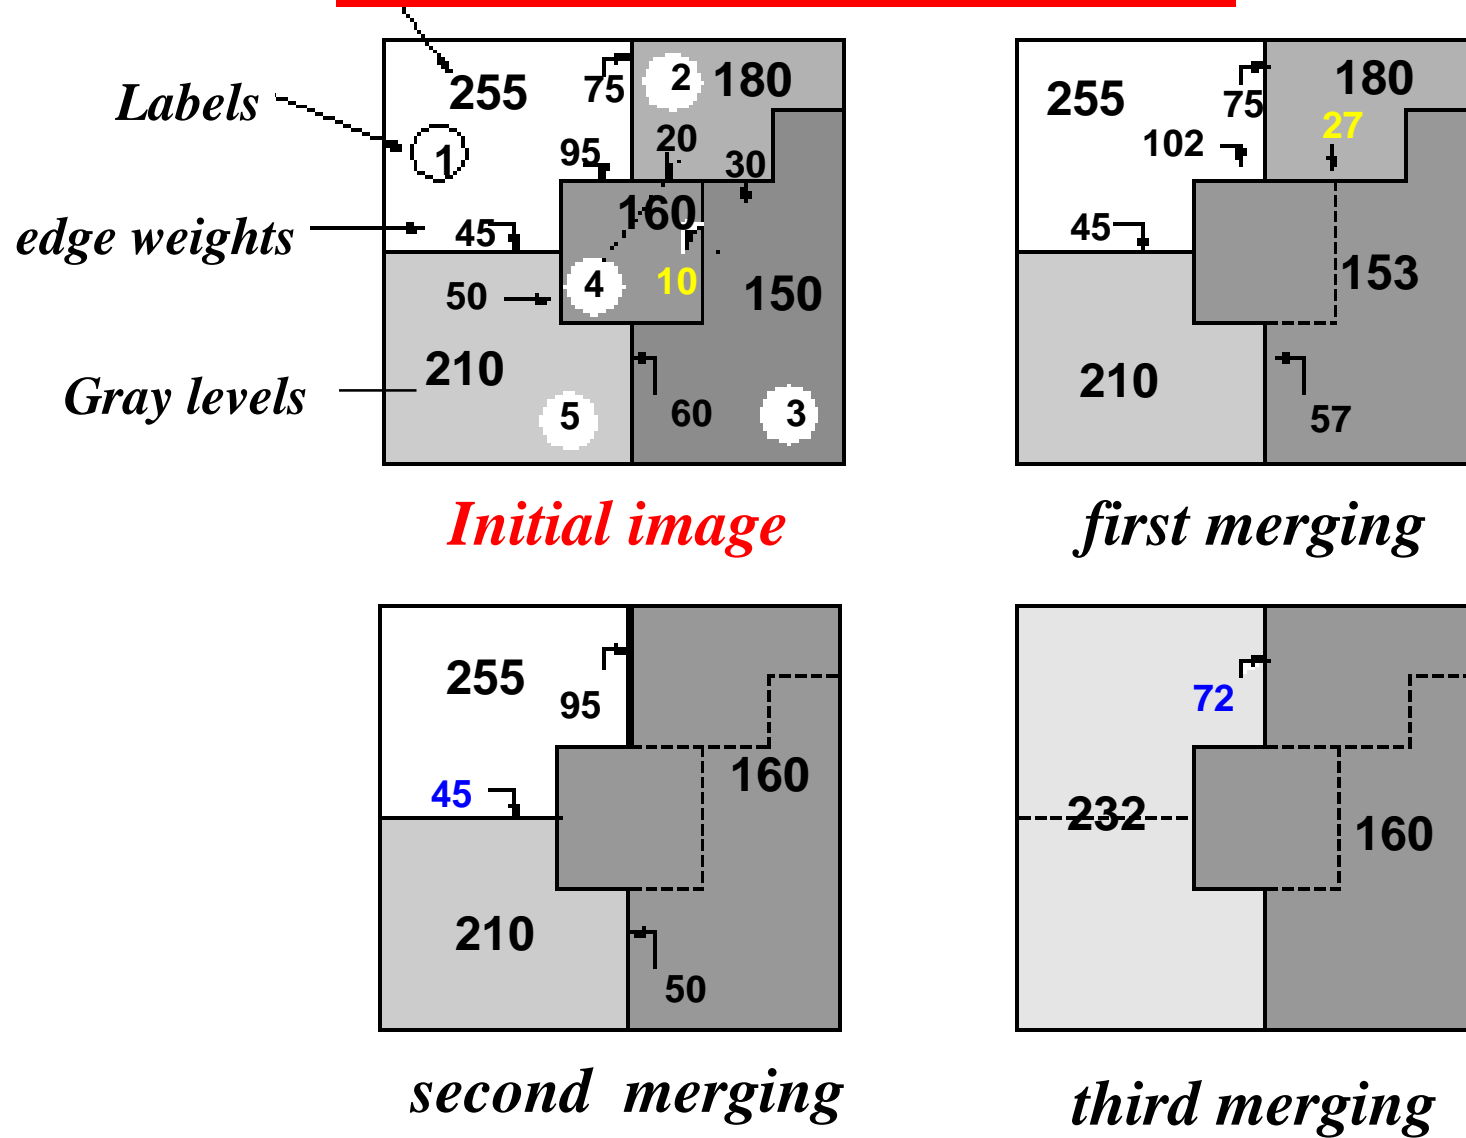

- **Properties :**

- Iterative process, where each iteration provides a partition coarser than the previous one:

$$P_0 \preceq P_1 \preceq P_2 \preceq \dots \preceq P_n,$$

- where  $P_{i+1}$  has exactly one region less than  $P_i$

# REGION MERGING (II)

## REGION MERGING (III)

- **Advantages**

- solves the resolution problem;
- works at the level of the flat zone;
- merges iteratively the two regions which are the more similar, without introducing a priori markers;
- generates nested partitions on which decision trees may be designed.

- **Drawbacks**

- demands the re-evaluation of all borders at each step;
- provokes leak effects (*i.e.* parasite additional lines)

# EXHAUSTIVE MERGING ALGORITHM

- **Initialisation:**
  - Introduce a quality criterion  $\kappa$  and a stop criterion  $\sigma$ ;
- **Elementary step:**
  - Attempt to merge separately each pair of adjacent regions, and evaluate criterion  $\kappa$  in each case;
  - find out "the" best pair with respect to  $\kappa$
  - actually merge this pair;
  - re-evaluate the borders around the new region;
- **Iteration:**
  - iterate until the stop criterion  $\sigma$  is reached.

# SUB-OPTIMAL MERGING ALGORITHM

- **Initialisation:**
  - Introduce a **local** criterion  $\lambda$  ( e.g. local contrast), a quality criterion  $\kappa$  and a stop criterion  $\sigma$ ;
- **Elementary step:**
  - Evaluate  $\lambda$  for each border of adjacent regions, and keep "the" lower one;
  - check whether the merging preserves criterion  $\kappa$ . If so, merge the two regions ; if not take the second smaller  $\lambda$  , etc..
  - re-evaluate the borders around the new region;
- **Iteration:**
  - iterate until the stop criterion  $\sigma$  is reached. Note that the pairs that don't preserve  $\kappa$  will stay disjoint in the final segmentation

# RAW APPLICATION OF THE ALGORITHM

*original image*

*segmentation into  
1262 regions,...*

*...among which,  
1080 isolated pixels*

Here, "raw" means without re-actualisation of the borders, and without pre-filtering. Note the considerable amount of regions reduced to one pixel.

# 1rst IMPROVMENT : RE-EVALUATIONS

initial valuation

new valuation

*initial image*

*segmentation into 550 regions*

*including 422 isolated pixels*

The re-evaluations return correct greys, but isolated pixels are still there.

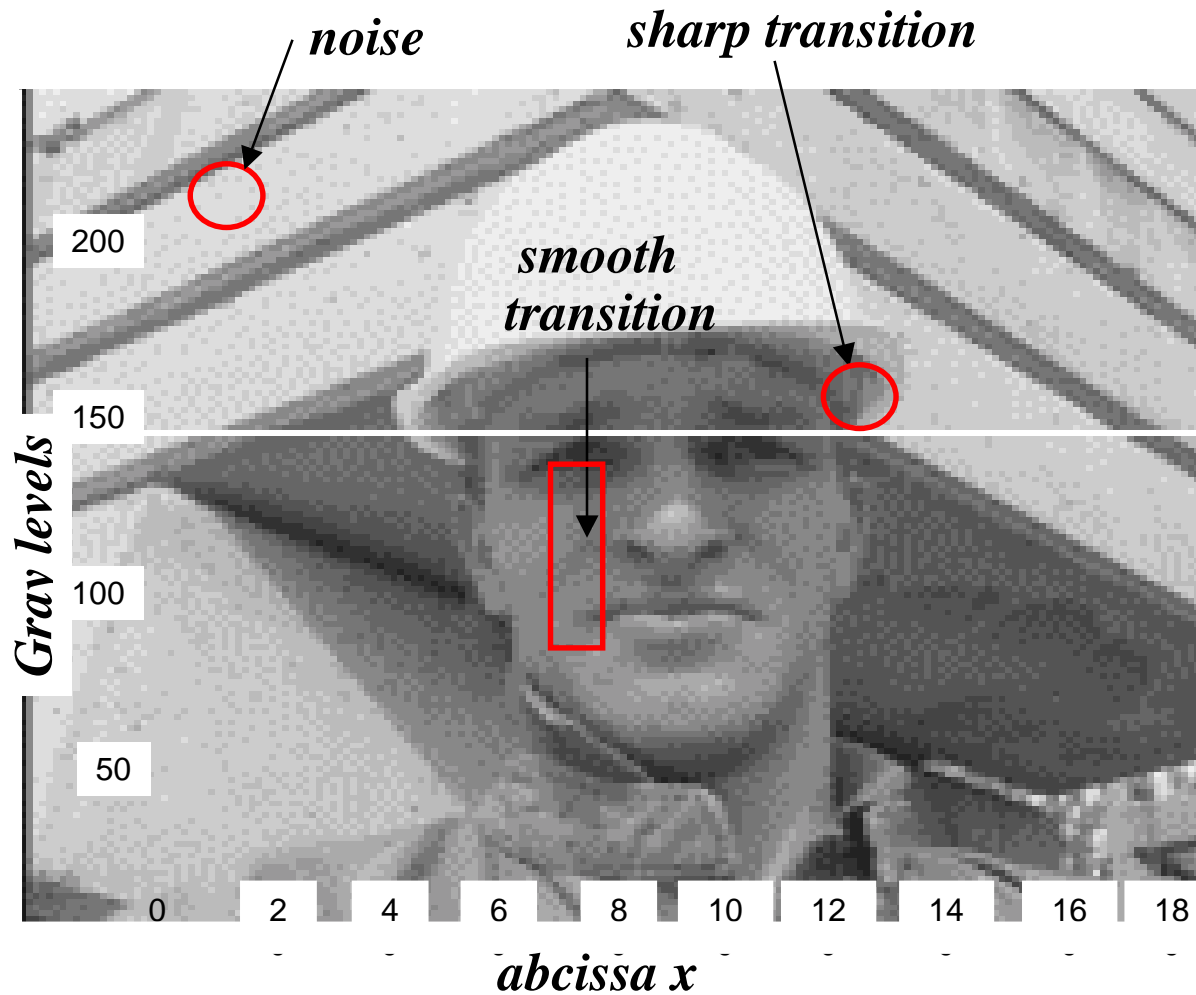

# GRAY PROFILE ALONG LINE 59

*abscissa x*

# ANALYSIS OF THE PROFILE

**Conclusion:** necessity of a pre-processing

# PRE-PROCESSING

- **Goal :**

- The goal of the pre-processing is to suppress non significant features in the image, which disturb the segmentation.

- **Means :**

- Treat separately the small peaks (and sinks), and the small or narrow steps :

# EXAMPLE OF PRE-PROCESSING

*Initial image*

*Filtered image*

*Small steps (in black)*

*Result of the pre-processing (735 regions)*

## CRITERIA FOR FUSION

- **Contrast:**
  - difference between the mean gray values of two adjacent regions;
- **Local contrast :**
  - contrast in a stripe centred along the border;
- **Texture :**
  - similitude with respect to a given model of texture.

# LOCAL CONTRAST

## LOCAL CONTRAST: AN EXAMPLE

*averaged gray levels*

*99 regions  
4966 contour points*

# FUSION BY TEXTURE

Ovoids splitting regions relevant on a same texture model

*99 regions*

*points*

*11352 bits*

*31.83 dB*

# SEGMENTATION OF SEQUENCES

{ Merging of regions → avoids a choice of markers  
Markers → ensures stability

## REGION MERGING UNDER MARKERS

**Cross criterion:** Any pair of neighbour regions may merge, unless both are marked.

	<i>markers growth</i>	<i>region merging under markers</i>
marker / non marker	<b>merging allowed</b>	<b>merging allowed</b>
non marker / non marker	<b>merging forbidden</b>	<b>merging allowed</b>
marker / marker	<b>merging forbidden</b>	<b>merging forbidden</b>

By comparison with pure marker growth, the above cross criterion is more flexible, and allows generation of new regions.

# TIME PRIORITARY MERGING

- **Sequences case :**

- Merging under markers is a general approach. In case of sequences, it is implemented **recursively**.
- The regions of segmentation  $t-1$  serve as markers at step  $t$  ;
- Image  $t$  is then processed by merging under markers.

- **Priority merging :**

- One merges in priority the  $t$ -regions that are included in an already segmented region of time  $t-1$ . This ensures **stability**;
- New regions (with respect to segmentation  $t-1$ ) are then generated by pure merging process at time  $t$  : **versatility**.

# GEOMETRICAL INTERPRETATION

The recursive procedure leads to two types of mergings :

In **prioritary merging** , the shape deformations are processed first.

## 3-D PRE-PROCESSING (I)

The sequence is filtered by *closing*  $\circ$  *opening* with respect to the volume of the "flat" zones in 3D

*Two successive  
initial images*

*The two filtered  
versions*

## 3-D PRE-PROCESSING (II)

The small transitions are stuck together by 2D marker growing, *i.e.* image by image.
